Chapter 8. Electricity and Magnetism: Current Electricity

PAGE NO: 312

Solution 1:
The flow of electrons in a particular direction in a conductor is called an electric current.

Solution 2:
An electric cell is the source of electric current in which chemical energy changes to electrical energy.

Solution 3:
The charge on an electron is -1.6×10^{-19} C.

Solution 4:
The constituents of cell are two electrodes in the form of conducting rods immersed in the solution called electrolyte.

Solution 5:

- S. I unit of electric current is Ampere
- S.I unit of potential difference is volt.
- S.I unit of resistance is ohm.

Solution 6:
I = 1A
T = 1s.
I = Q/t = ne/t
So, $n = I.t/e = 1.1/(1.6 \times 10^{-19}) = 6.25 \times 10^{18}$ electrons.

Solution 7:
I = Q/t = 0.7 / 7 = 0.1 Ampere.

Solution 8:
Rheostat is used to control the current in the circuit.

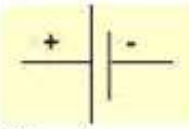
PAGE NO : 313

Solution 9:
Rheostat is the variable name of electrical resistance.

Solution 10:
Switch is used to put the current on and off in the circuit.

Solution 11:

(i) Cell - Cell provide an electric current in the circuit.

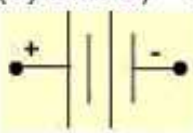


(ii) Ammeter – It is a device to measure an electric current in the circuit.

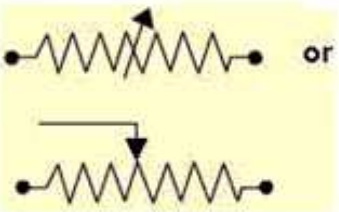
(iii) Voltmeter – It is used to measure the potential difference between two points in the circuit.

(iv) Key – It is used to put the current on and off in the circuit.

(v) Battery – It is used to charge the cell.



(vi) Rheostat – it is used to control the electric current in the circuit.



Solution 12:

I = Q/ t So, Q = I.t = 1.2 x 3.0 = 3.6 C.

Solution 13:

A – is a voltmeter to measure the potential difference, B is an electric resistance to control the current in the circuit , C is the ammeter to measure the magnitude of an electric current, D is cell to provide electric current in circuit, E is an electric key to on and off the circuit, F is the rheostat to control the current in circuit.

Solution 14:

The slope of the graph represents that with current flowing through a conductor is directly proportional to the potential difference applied the resistance of conductor is constant.

Solution 15:

Potential difference between two conductors is defined as the amount of work done in moving the unit positive charge from one conductor to another through the wire.

Solution 16:

Yes, electric current is a scalar quantity.

Solution 17:

The electric resistance of the wire depends on the following factors :

- The length of the wire.
- The area of cross-section of the wire.
- The temperature of the wire.
- The material of the wire.

Solution 18:
The S.I unit of resistance is ohm.

Solution 19:
If another bulb is connected in series then the resistance of the wire will increase.
If another bulb is connected in parallel then resistance will decrease.

Solution 20:
V = IR.

Solution 21:
The resistance of the wire is 2 ohms if a current of 1 ampere flows through it when the potential difference across it is 2 volt.

Solution 22:
The current I = V/R = 14/28 = 0.5 Ampere.

Solution 23:
The factors on which resistance of the wire depends are:

- The length of the wire , resistance is directly proportional to the length of wire.
- The cross-section of the wire , resistance is inversely proportional to the cross-section of the wire.
- The temperature of the wire , resistance of wire is directly proportional to the temperature of the wire.
- The material of the wire (good conductors possess less resistance.)

Solution 24:
W = V.Q = 6.3 = 18 Joule.

Solution 25:
The resistance of the conductor is the property due to which it opposes the flow of current in it.

Solution 26:
The potential difference between two points is 1 volt if the work done in transferring 1 coulomb of charge from one point to another point is 1 joule.
